

Talnira — Evidence-Based Career & Hiring Intelligence

The problem I keep coming back to:

Capable candidates still get filtered out because their resumes don't clearly show their fit for a specific role. Resume optimization has turned into a keyword game, where people match words from a job description instead of showing what they can actually do.

Take a candidate who genuinely knows Python, ML, and LLMs and has built relevant projects. If that evidence isn't connected to what the job asks for, they can still be overlooked. So I don't think the question should be "How many keywords are present?" It should be "What evidence does this candidate have for this job?"

What Talnira does:

Talnira moves from keyword matching to evidence-based job matching. For each requirement in a job description, it looks at the candidate's evidence and gives one of three verdicts:

- Proven: credible evidence exists.
- Weak: the skill is present, but the evidence is limited.
- Missing: there is no supporting evidence.

It then helps candidates improve their resumes without inventing skills, metrics, experience, or achievements. The goal isn't to manipulate ATS systems. It's to make a candidate's real capabilities easier to understand.

Evidence beyond the resume:

A resume is only a candidate's own description of themselves, so with the candidate's permission I want Talnira to eventually look at two more sources:

- GitHub analysis: repositories, the languages and tools actually used, project complexity, commit history and consistency, README and documentation quality, and whether the projects listed on the resume really exist and match what's claimed. For example, if a resume says "built an LLM-based application," the analysis would check whether there's a real repository showing it.
- LinkedIn analysis: work history and timeline, roles and responsibilities, certifications, recommendations, and whether the profile is consistent with the resume. This would show where the resume undersells the candidate and where the two sources disagree.

These sources wouldn't automatically prove a skill. They'd give additional context, tied back to specific job requirements, so a "Weak" requirement could become "Proven" when real evidence supports it. The same analysis would help improve the resume by pointing out strong projects or experience the candidate forgot to include or explain.

The recruiter side:

The same intelligence can power a recruiter workflow:

1 Job Description + Resume Batch → AI Analysis → Explainable Matching → Shortlist

Instead of a black-box score, recruiters can see why a candidate matches and where the evidence is strong or weak. In short:

- Candidates ask: "How well do I actually fit this job?"
- Recruiters ask: "Which candidates have the strongest evidence, and why?"

What I learned today:

Your advice to solve a real problem instead of building an AI wrapper strongly resonated with me. I want to validate this with real candidates and recruiters, including whether they would actually pay for it, before expanding Talnira.

Your advice about involving stakeholders from Day 0 also changed my approach. I want to build with users, not in isolation.

Where I am now:

Talnira is at the MVP stage and not yet deployed. My immediate goal is validation with real candidates and recruiters.

Where I'd value your thoughts

1. Is this problem significant enough to build a company around?
2. What would you validate first?
3. Where could Talnira build real defensibility?
4. Should GitHub and LinkedIn evidence analysis be part of the initial product, or a later layer?

Thank you again, Sir, for your time and guidance. It meant a lot.

Warm regards,

Siddhartha
